

## 2025 Ch H2 Q8

**Section:** Chemistry in Society

**Topic:** Oxidising and Reducing Agents

### Question Summary

(a) Tin is extracted from  $\text{SnO}_2$  using carbon:  $\text{SnO}_2 + \text{C} \rightarrow \text{Sn} + \text{CO}_2$ . Three related calculations:

(i) Mass of  $\text{SnO}_2$  needed to obtain 100 g Sn at 64% yield.

(ii) Identify excess reactant when 25.2 g  $\text{SnO}_2$  reacts with 3.0 g C, and find moles left over.

(iii) From 26.5 litres of  $\text{CO}_2$  ( $80 \text{ L mol}^{-1}$ ), calculate the mass of  $\text{SnO}_2$  that reacted.

(b) From a magnesium extraction flow diagram: (i) separate  $\text{Mg}(\text{OH})_2(\text{s})$  from  $\text{CaCl}_2(\text{aq})$ ; (ii) suggest another profit maximisation besides recycling  $\text{Cl}_2$ .

### Worked Solution

**(a)(i)** Stoichiometry:  $1 \text{ mol SnO}_2 \rightarrow 1 \text{ mol Sn}$ .

Given GFM's:  $\text{SnO}_2 = 150.7 \text{ g}$ ;  $\text{Sn} = 118.7 \text{ g}$ .

At 100% yield, Sn mass from x g  $\text{SnO}_2$  is  $x * (118.7 / 150.7)$ .

At 64% yield, actual Sn =  $0.64 * [\text{theoretical Sn}]$ . To obtain 100 g Sn:

Theoretical Sn required =  $100 / 0.64 = 156.25 \text{ g}$ .

Corresponding  $\text{SnO}_2$  required =  $156.25 * (150.7 / 118.7) = \mathbf{198.4 \text{ g}}$  (3 s.f.).

**(a)(ii)** Moles:  $n(\text{SnO}_2) = 25.2 / 150.7 = 0.167 \text{ mol}$ ;  $n(\text{C}) = 3.0 / 12.0 = 0.250 \text{ mol}$ .

Reaction is 1:1, so  $\text{SnO}_2$  is limiting. Excess moles of C =  $0.250 - 0.167 = \mathbf{0.083 \text{ mol}}$ .

Excess reactant: **carbon**.

**(a)(iii)** Moles  $\text{CO}_2 = 26.5 \text{ L} / (80 \text{ L mol}^{-1}) = 0.33125 \text{ mol}$ .  
Mole ratio  $\text{SnO}_2:\text{CO}_2$  is 1:1, so moles  $\text{SnO}_2$  reacted = 0.33125 mol.

Mass  $\text{SnO}_2 = 0.33125 * 150.7 = \mathbf{49.92 \text{ g}}$  (2 d.p.).

**(b)(i)** Separate the solid  $\text{Mg}(\text{OH})_2$  from the  $\text{CaCl}_2$  solution by **filtration**.

**(b)(ii)** Profit can also be maximised because **seawater is a free/cheap raw material** (or by **selling  $\text{CaCl}_2$  as a by-product**).

### Final Answers

(a)(i) 198.4 g  $\text{SnO}_2$

(a)(ii) Excess: carbon; moles left unreacted = 0.083 mol

(a)(iii) 49.92 g  $\text{SnO}_2$

(b)(i) Filtration

(b)(ii) Seawater is free/cheap raw material (or sell  $\text{CaCl}_2$  by-product)

### Revision Tips

- For percentage yield problems: required theoretical product = actual / (%yield as a decimal).
- Always compare *moles* to find the limiting reagent and excess moles.
- Gas calculations at a given molar volume:  $n = V / V_m$ , then convert to mass via GFM.
- In industrial flowsheets, look for *separation of phases* (filtration) and *valuable by-products* to boost profitability.
